What is the polygon with 6 sides

Polygon consists of 6 sides Grande GIF886×1024, 11.2 KiBMedium GIF554×640, 7.2 KiBSmall GIF277×320, 3.7 KiB Polygons are some of the first forms we learn to draw as children, and appear around us. Polygons can be regular or irregular. They can be simple or complex, convex or concave. They can be the familiar forms you see in the textbooks of geometry, or they can be strange forms, such as darts and bowels. The word "polygon" means "very anguish", from Greek. To be a polygon, a flat and closed form should only use line segments to create its sides. So a circle or any form that has a curve is not a polygon. The three identifying properties of any polygon are that the polygon is: Two-dimensional shape Closure in a space (have an interior and exterior) Made with straight sides Types of polygons Let's take a look at the wide range of shapes that are polygons and go in detail. A convex polygon does not have an internal angle greater than 180° (it has no sides towards the inside). A concave polygon has an internal angle greater than 180°. A simple polygon encloses a single internal space (abundant) and has no self-intersecting sides. Complex polygons have self-intersecting sides! An irregular polygon has no congruent sides and internal corners. A regular polygon has congruent sides and internal corners. Regular and irregular polygons Regular polygons have congruent sides and internal corners. Each side is equal in length to each other side, and each inner corner isto all other internal corners. The number of regular polygons is unlimited. The irregular polygons have no sides and congruent angles. Home plates on a softball or baseball field is an irregular pentagon, because it has five sides with two corners of 90°. Convex and concave polygons A convex polygon closes in an internal area without looking at dented. None of his inner corners point to the inside. In geometry, you could have a four-sided polygon pointing out in all directions, like a kite, or you could have the same four sides so that two of them point to the inside, forming a dart. The kite is convex; The dart is concave. Each inner corner of a convex polygon is less than 180°. A concave polygon has at least one angle greater than 180°. Think of a simple hexagon in the form of bowels (6 sides.) It will have two internal angles greater than 180°. Simple and complex polygons Simple polygons have no self-intersecting sides. Complex polygons, also called self-intersecting polygons, have sides crossing each other. The classic star is a complex polygon. Most people can doodle a star on paper quickly, but few people label it a pentagram, complex polygon, or self-intersecting polygon. The complex star-shaped polygon family generally share the prefix of the Greek number and use the suffix -gram: pentagram, hexagram, ottagram, and so on. You can't draw a complex triangle. For each polygon with four or more sides, a complex polygon can be drawn. A complex quadrilateral is that family itchingbut it is considered to have only four sides, because a couple of opposite sides twisted to cross. just as you do not count the crossed sides as four segments of line, do not count the two corners that create as internal corners. the quadrilateral complex has only four sides and four internal corners. complex polygons can be difficult to imagine unless you think about them with elastic sides. If you could raise part of the polygon up and twist it, so two sides cross each other, and then put it down again flat, you would have a complex polygon, because you turned two sides, you still have those two sides (they do not double in number crossing.) also do not create new vertices where they cross. antiparallele a unusual complex polygon is the antiparallelogram, which seems a little like bird wings. an antiparallelogram (or cross-platform) has the normal two pairs of congruent sides, opposite, but a pair has been crossed, forming what seems to be two touching triangles. like any parallelogram, however, the antiparallelogram has only four sides and four internal corners. its diagonals, however, are located outside the shape! polygon names of polygons shape polygon number of triangle sides 3 square sides 4 sides rectangle 4 sides quadrilateral 4 sides parallelogram 4 sides rhodogram 4 sides 4 sides kite 4 sides pentagon 5 sides hexagon 6 sides eptagon 7 sides octagon 8 sides nonagon 9 sides dodecagon 10 sidesEctagon 100 sides n-gon n-sides is a polygon? The interiors of all polygons can be divided into triangles, which is a practical way to find the sum of their inner corners. Take two less than the number of sides, n, and multiply the times 180°: (n - 2) x 180°. A circle is not a polygon, but an icosikaihenagon is a polygon. An icosikaihenagon is a 21-sided polygon. Most mathematical and mathematical students would simply write "21-gon" to name it. Polygons can be studied and classified in many different ways. Now you see that polygons can be regular or irregular, convex or concave, and simple or complex. When you see an unfamiliar polygon, you can determine its properties and classify it correctly. To be a polygon, the shape must be flat, close in a space, and be made using only the right sides. Polygons with congruent sides and corners are regular; All the others are irregular. Polygons with all the inner corners below 180° are convex; If a polygon has at least one inner angle greater than 180°, it is concave. Simple polygons do not cross their sides; complex polygons have self-intersecting sides. Polygons are around you! Next lesson: What is a regular range?
